CSC 347 - Concepts of Programming Languages

Folds

Instructor: Stefan Mitsch

Learning Objectives

❓ How to combine collection elements into an aggregate result?

- Understand folds

Exercise: Sum the Elements of a List

❓ Express in an imperative style

Java

```
int sum (List<Int> xs) {
  int result = 0;
  for (int i = 0; i < xs.length; i++)
    result += xs.get(i);
  return result;
}
```

Scala

```
def sum (xs:List[Int]) : Int =
  var result = 0
  for i <- 0 until xs.length do
    result = result + xs(i)
```

Exercise: Sum the Elements of a List

Express in a functional style

```
def sum (xs:List[Int])              : Int =  xs match
  case Nil    => 0
  case y::ys => y + sum (ys)

val xs = List(11,21,31)
sum (xs)
```

```
sum(11::21::31::Nil)
--> sum(11::21::31::Nil)
--> 11 + sum(21::31::Nil)
--> 11 + (21 + sum(31::Nil))
--> 11 + (21 + (31 + sum(Nil)))
--> 11 + (21 + (31 + 0))
--> 11 + (21 + 31)
--> 11 + 52
--> 63 = (11 + (21 + (31 + 0)))
```

Exercise: Sum the Elements of a List

❓ With a different zero element

```
def sum (xs:List[Int], z:Int = 0) : Int =  xs match
  case Nil   => z
  case y::ys => y + sum (ys, z)

val xs = List(11,21,31)
sum (xs)
```

```
sum(11::21::31::Nil)
--> sum(11::21::31::Nil, 0)
--> 11 + sum(21::31::Nil, 0)
--> 11 + (21 + sum(31::Nil, 0))
--> 11 + (21 + (31 + sum(Nil, 0)))
--> 11 + (21 + (31 + 0))
--> 11 + (21 + 31)
--> 11 + 52
--> 63 = (11 + (21 + (31 + 0)))
```

Exercise: Sum the Elements of a List

❓ Sum of elements in a list computing forward

```
def sum (xs:List[Int], z:Int = 0) : Int =  xs match
  case Nil   => z
  case y::ys => sum (ys, z + y)

val xs = List(11,21,31)
sum (xs)
```

```
sum(11::21::31::Nil)
--> sum(11::21::31::Nil, 0)
--> sum(21::31::Nil, 11)
--> sum(31::Nil, 32)
--> sum(Nil, 63)
-->
-->
-->
--> 63 = (((0 + 11) + 21) + 31)
```

Folds

💡 generalize the `+` operation

```
def sum       (xs:List[Int], z:Int)                    : Int =
  xs match
    case Nil   => z
    case y::ys => sum       (ys, z + y)

val xs = List(11,21,31)
sum       (xs, 0)
```

Folds

generalize the `+` operation

```
def foldLeft  (xs:List[Int], z:Int, f:((Int,Int)=>Int)) : Int =
  xs match
    case Nil    => z
    case y::ys => foldLeft  (ys, f(z,y), f)

val xs = List(11,21,31)
foldLeft  (xs, 0, _+_)
```

Folds

❓ Change the return type

```
def foldLeft  (xs:List[Int], z:String, f:(String,Int)=>String) : String =
  xs match
    case Nil    => z
    case y::ys => foldLeft  (ys, f(z, y), f)

val xs = List(11,21,31)
foldLeft  (xs, "", _ + " " + _)
```

Folds

❓ Changing the parameter type

```
def foldLeft  (xs:List[List[Int]], z:Int, f:(Int,List[Int])=>Int) : Int =
  xs match
    case Nil    => z
    case y::ys => foldLeft  (ys, f(z, y), f)

val xss = List(List(11,21,31),List(),List(41,51))
foldLeft  (xss, 0, _ + _.length)
```

Folds

💡 Abstracting the type

```
def foldLeft  [Z,X] (xs:List[X], z:Z, f:((Z,X)=>Z)) : Z =
  xs match
    case Nil    => z
    case y::ys => foldLeft  (ys, f(z,y), f)

val xs = List(11,21,31)
foldLeft  (xs, "!", (z:String,x:Int) => z + " " + x)
```

```
res1: String = ! 11 21 31
```

Fold Left vs. Fold Right

Fold Left

```
def foldLeft  [Z,X] (xs:List[X], z:Z, f:((Z,X)=>Z)) : Z =
  xs match
    case Nil    => z
    case y::ys => foldLeft  (ys, f(z,y), f)

val xs = List(11,21,31)
foldLeft  (xs, "!", (z:String,x:Int) => z + " " + x)
```

```
res1: String = ! 11 21 31
```

Fold Right

```
def foldRight [X,Z] (xs:List[X], z:Z, f:((X,Z)=>Z)) : Z =
  xs match
    case Nil    => z
    case y::ys => f (y, foldRight (ys, z, f))

val xs = List(11,21,31)
foldRight (xs, "!", (x:Int,z:String) => x + " " + z)
```

```
res1: String = 11 21 31 !
```

Folds Builtin in Lists

- Scala `List` class has `fold` methods (curried!)

```
xss.foldLeft (0) ((z,xs)=>z + xs.length)
```

Fold Left vs. Fold Right

```
def foldLeft [Z,X] (xs:List[X], z:Z, f:((Z,X)=>Z)) : Z =  xs match {
  case Nil    => z
  case y::ys => foldLeft  (ys, f(z,y), f)
}
```

```
def foldRight [X,Z] (xs:List[X], z:Z, f:((X,Z)=>Z)) : Z =  xs match {
  case Nil    => z
  case y::ys => f (y, foldRight (ys, z, f))
}
```

- `foldLeft` is *tail recursive*: `return foldLeft (ys, f(z, y))`
  - apply `f` to the head and the accumulated result
  - recursive call on the tail
  - base case used with first element
- `foldRight` is *recursive into an argument*:
  - `return f (y, foldRight (ys, z))`
  - recursive call on the tail
  - apply `f` to the head and result of recursion
  - base case used with last element

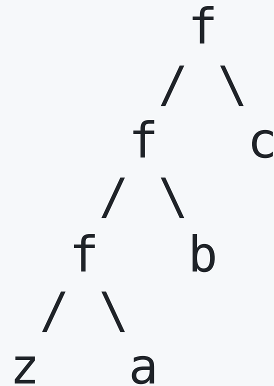
Fold Left vs. Fold Right

```scala
def foldLeft [Z,X] (xs:List[X], z:Z, f:((Z,X)=>Z)) : Z =  xs match
  case Nil   => z
  case y::ys => foldLeft (ys, f(z,y), f)
```

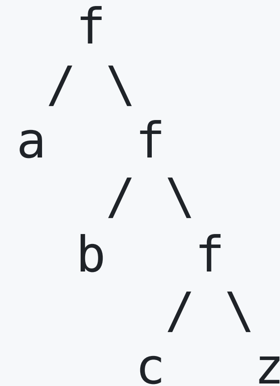
```scala
def foldRight [X,Z] (xs:List[X], z:Z, f:((X,Z)=>Z)) : Z =  xs match
  case Nil   => z
  case y::ys => f (y, foldRight (ys, z, f))
```

```scala
val xs = List(a, b, c)
foldLeft (xs, z, f) === f( f( f(z,a),b),c)
foldRight(xs, z, f) === f(a, f(b, f(c,z)))
```

```
xs.foldLeft(z)(f)
```



```
xs.foldRight(z)(f)
```



Folds are Universal

```
def sum          (xs: List[Int])               = xs.foldLeft(0)(_+_)
def prod         (xs: List[Int])               = xs.foldLeft(1)(_*_)
def or           (xs: List[Boolean])           = xs.foldLeft(false)(_||_)
def and          (xs: List[Boolean])           = xs.foldLeft(true)(_&&_)
def append  [X]  (xs: List[X])(ys: List[X])    = xs.foldRight(ys)(_::_)
def flatten [X]  (xs: List[List[X]])           = xs.foldLeft(Nil:List[X])(_:::_)
def length  [X]  (xs: List[X])                 = xs.foldLeft(0)((z,x)=>z+1)
def reverse [X]  (xs: List[X])                 = xs.foldRight(Nil:List[X])((x,zs)=>zs:::List(x))
def map    [X,Y] (xs: List[X], f: X=>Y)        = xs.foldRight(Nil:List[Y])(f(_)::_)
def filter  [X]  (xs: List[X], f: X=>Boolean) = xs.foldRight(Nil:List[X])((x,zs)=>if f(x) then x::zs else zs)
```

- Lots of examples
- Tutorial on universality of folds

Summary

- Folds are universal functions to combine list elements into an aggregate result
- `foldRight` folds from the right (zero element combined with last element)
- `foldLeft` folds from the left (zero element combined with list head)
